Sample Questions and Their Detailed Answers

Below, we analyze representative questions, their answers, and implications for mastery of molecular biology concepts as presented in Lodish.

1. Describe the process of DNA replication in eukaryotic cells, emphasizing the roles of key enzymes.

Answer:

DNA replication in eukaryotic cells is a highly coordinated, semi-conservative process involving multiple enzymes and regulatory factors. The process can be summarized in several stages:

- Initiation: Replication begins at origins of replication, where the Origin Recognition Complex (ORC) marks sites for assembly. Licensing factors, such as Cdc6 and Cdt1, facilitate the loading of the Minichromosome Maintenance (MCM) helicase complex onto DNA, forming the pre-replication complex during G1 phase.

- Unwinding: During S phase, activation of helicases unwinds the DNA strands, creating replication forks. DNA helicase (e.g., MCM complex) separates the strands, aided by single-strand binding proteins (SSBs) that stabilize the unwound DNA.

- Primer Synthesis: DNA primase synthesizes short RNA primers complementary to the DNA template, providing a starting point for DNA polymerases.

- Elongation: DNA polymerase α and δ synthesize new strands in the 5' to 3' direction. DNA polymerase δ primarily synthesizes the lagging strand, while DNA polymerase α synthesizes the leading strand.

- Lagging Strand Synthesis: Okazaki fragments are synthesized discontinuously, each initiated by primers, and later joined by DNA ligase.

- Termination and Recycling: DNA polymerases have proofreading activity to ensure fidelity. The replication machinery disassembles after replication, and telomerase extends the telomeres in certain cell types.

Key Enzymes and Their Roles:

- DNA Helicase (MCM complex): Unwinds DNA at replication forks.

- Primase: Synthesizes RNA primers.
- DNA Polymerases (α and β): Extend DNA strands with high fidelity.
- DNA Ligase: Joins Okazaki fragments.
- Telomerase: Extends telomeres to prevent shortening.

This detailed understanding aligns with the descriptions and diagrams provided in Lodish, emphasizing the importance of enzyme coordination for accurate DNA duplication.

2. Explain the mechanism of transcription initiation in eukaryotic cells, including the roles of transcription factors and RNA polymerase II.

Answer:

Transcription initiation in eukaryotic cells involves a complex assembly of proteins and DNA elements to accurately transcribe genes into messenger RNA (mRNA):

- Promoter Recognition: The core promoter region, often containing a TATA box (~25-30 bp upstream), serves as the binding site for transcription machinery.
- Assembly of the Pre-Initiation Complex (PIC):
 - General transcription factors (GTFs) such as TFIID, which contains the TATA-binding protein (TBP), bind to the TATA box.
 - Other GTFs (TFIIB, TFIIF, TFII E, TFII H) sequentially assemble, guiding RNA polymerase II to the promoter.
- Role of Transcription Factors:
 - TATA-binding protein (TBP): Binds TATA box, bending DNA to facilitate PIC assembly.
 - Activator proteins: Bind enhancer regions, recruiting coactivators and GTFs.
 - Mediator complex: Acts as a bridge between activators and the PIC, facilitating communication and stabilization.
- Initiation of Transcription:

- TFIIF phosphorylates the C-terminal domain (CTD) of RNA polymerase II, causing conformational changes that release the enzyme from GTFs.
- RNA polymerase II begins synthesizing RNA in the 5' to 3' direction, starting at the transcription start site.

Summary of Key Steps:

- GTFs assemble at the promoter.
- RNA polymerase II is recruited and positioned.
- Phosphorylation of RNA polymerase II's CTD triggers transition to elongation.

Lodish provides detailed diagrams illustrating the steps and molecular interactions, emphasizing the regulation of transcription initiation by multiple factors.

3. What is the role of chromatin remodeling in gene expression, and which complexes are involved?

Answer:

Chromatin remodeling is essential for regulating gene expression by altering the accessibility of DNA to transcription factors and polymerases. Since DNA is packaged into nucleosomes—a repeating unit of DNA wrapped around histone proteins—modifications and repositioning are necessary for transcriptional activation.

Roles of Chromatin Remodeling:

- Facilitate or hinder access to DNA sequences, thereby controlling which genes are expressed.
- Allow binding of transcription factors and the assembly of transcriptional machinery.
- Play roles in processes like DNA replication, repair, and recombination.

Major Chromatin Remodeling Complexes:

- SWI/SNF: Uses ATP hydrolysis to slide or eject nucleosomes, exposing promoter regions.
- ISWI: Involved in nucleosome spacing and chromatin assembly.
- CHD: Modulates chromatin structure during transcription and development.
- INO80: Facilitates nucleosome eviction and exchange.

Histone Modifications:

- Acetylation, methylation, phosphorylation, and ubiquitination of histone tails influence chromatin structure and are recognized by specific binding proteins that recruit additional factors.

Mechanism:

- Remodeling complexes are recruited by transcription factors or histone modifications.
- They induce conformational changes, either repositioning nucleosomes or modifying histones, to enable transcriptional activation.

Lodish discusses these complexes in the context of gene regulation, illustrating their importance through experimental evidence and models.
