- Relay (commonly a 5V or 12V relay)
- Voltage sensing circuitry (voltage divider or comparator)
- Power supply (matching the battery voltage)
- Charging source (such as a power adapter or solar panel)
- Protection components (diodes, resistors, capacitors)

The circuit operates by monitoring the battery voltage and controlling the relay to connect or disconnect the charger accordingly.

Operation Modes

The circuit generally works in two primary modes:

- Charging Mode
 - When the battery voltage drops below a set threshold, the NE555 timer outputs a high signal.
 - This energizes the relay coil, closing the contacts.
 - The charging source supplies current to the battery.
- Maintenance/Float Mode

- When the battery reaches the desired full charge voltage, the sensing circuitry triggers the NE555 output to go low.
- The relay de-energizes, disconnecting the charging source.
- The system maintains the battery at a safe, float charge level, preventing overcharging.

Step-by-Step Explanation of Circuit Operation

- Voltage Sensing
 - A voltage divider reduces the battery voltage to a safe level for comparison.
 - A reference voltage (possibly from a Zener diode or a voltage regulator) is used to set the threshold.
- Triggering the NE555 Timer
 - When the sensed voltage is below the threshold, the NE555 is configured to output a high signal.
 - This output energizes the relay coil via a transistor or driver circuit.
- Relay Activation
 - The relay closes its contacts, enabling the charging current flow to the battery.
 - During charging, the system actively monitors the voltage.
- Automatic Disconnection
 - Once the battery reaches the full charge voltage, the sensing circuit disables the NE555 output.

- The relay de-energizes, disconnecting the charger.
- The system remains in standby mode, preventing overcharging.
