Preparation and Setup for the ANSYS CFX Wind Turbine Blade Simulation

A successful CFD simulation hinges on meticulous preparation. Here's a step-by-step overview:

1. Geometry Creation and Import

- Designing the Blade Geometry: Start with a detailed CAD model of the wind turbine blade. This can be created using CAD software like SolidWorks, CATIA, or Siemens NX, or sourced from existing design databases.
- Simplification: Ensure the geometry is simplified to remove unnecessary small features that won't significantly affect flow but could complicate meshing.
- Importing into ANSYS Workbench: Use the 'External Model' component to import your geometry into ANSYS Workbench for simulation setup.

2. Domain and Boundary Definitions

- Define the Computational Domain: Typically, a cylindrical or rectangular domain encompassing the blade is used to simulate the airflow. The domain should be large enough (at least 10-20 times the blade length upstream and downstream, and 5 times the blade height in cross-section) to minimize boundary effects.
- Boundary Conditions:
 - Inlet: Set as velocity inlet with specified wind speed (e.g., 12 m/s).
 - Outlet: Use a pressure outlet boundary condition.
 - Walls: Blade surfaces are modeled as stationary or rotating walls, depending on the simulation type.

- Symmetry or Periodic Boundaries: Apply where applicable to reduce computational load.

3. Mesh Generation

- Meshing Strategy:
 - Use a combination of structured (hexahedral) and unstructured (tetrahedral or prism layers) meshes.
 - Focus on high-quality mesh near the blade surfaces to accurately capture boundary layer effects.
 - Prism Layers: Implement boundary layer prism layers to resolve near-wall turbulence accurately.
 - Mesh Refinement: Conduct mesh independence studies to ensure results are not sensitive to mesh size.

- Flow Regime: Typically, incompressible flow assumptions are valid for wind speeds under Mach 0.3.
- Rotating vs. Stationary: For detailed blade analysis, you can model the blade as rotating to simulate actual operational conditions (using the 'Moving Reference Frame' approach) or analyze a stationary blade at different angles (for static analysis).

2. Boundary Conditions

- Inlet: Velocity inlet with specified wind speed and turbulence intensity.
- Outlet: Pressure outlet at atmospheric pressure.
- Blade Surface: No-slip wall boundary condition.
- Additional Boundaries: Symmetry or periodic boundaries as needed.

3. Material and Fluid Properties

- Use air properties at the operating temperature and pressure, typically standard atmospheric conditions.

4. Solver Settings

- Solution Type: Steady-state for initial analysis; transient simulations for detailed unsteady effects.

- Convergence Criteria: Set residuals to acceptable levels (e.g., $1e-5$) and monitor key parameters like torque and lift/drag coefficients.
